Ticks fauna of sheep and goats in some suburbs of Mazandaran province, Iran

Ebrahimzadeh, E.*, Pazhoom, F., Nabian, S., Shayan, P., Bakhshani, A.

Department of Parasitology and Tick and Tick Born Diseases Center, Faculty of Veterinary Medicine, University of Tehran, Tehran, Iran

**Introduction**

Ticks are serious threat to the health of animals and human beings. They are haematophagous arthropods that can cause paralysis, anemia, skin irritation, and pathogen transmission. Important pathogens such as CCHF virus, *Anaplasma* spp, *Ehrichia* spp, *Babesia* spp, and *Theileria* spp could be transmitted by various species of ticks.

Mazandaran province has a humid climate, which is favourable to animal husbandry such as sheep breeding. Due to humid climate, the likelihood of exposure to tick infestation is increasing.

**Materials and Methods**

The area of study was Mazandaran province, which is located in the north of Iran. The province had an average temperature of 25°C in summer and about...
9°C in winter, and the annual rainfall averages 615 mm in the eastern part of Mazandaran province and more than 886 mm in the western part in last year (2012). According to Iran Veterinary Organization, 2,023,260 sheep and 217,260 goats have been reported in 2011.

During the first 7 months of 2012, a total of 1351 animals (sheep and goats) from 23 different points of Mazandaran province were inspected. The tick samples were collected from the whole body of infested sheep and goats in some suburbs of Mazandaran province including 8 points from Ghaemshahr, 6 points from Sari, 2 points from Babol, 2 points from Mahmooodabad, 5 points from Savadkooh. In this study, Kou estakhr is the most mountainous area that is located in savadkooh with 1770 m above the sea level and Gol neshin is the low-laying area that is located near Sari. The height of other location is placed between 2 these points. Tick samples were counted and separately preserved in 70% ethanol. Adult male ticks were identified under a stereomicroscope, according to the identification keys (Mazlum, 1968, 1971; Walker et al., 2003; Estrada-Pena et al., 2004).

Results

In the present study, 321 (23.76%) out of the total 1351 inspected sheep and goats were infested with ticks. A total of 1190 ticks (590 female and 600 male) were collected from 321 animals (273 sheep and 48 goats). The occurrence of ticks on sheep and goats were 26% and 15.7%, respectively. Many inspected sheep and goats were free of ticks due to indiscriminate use of Ivermectin. Six genera including Rhipicephalus, Haemaphysalis, Hyalomma, Dermacentor, and Ixodes were determined in this study. The identified tick specimens belonged to six Genus and 11 species, including Rhipicephalus turanicus (47%), Rhipicephalus bursa (24.6%), Haemaphysalis punctata (17.16%), Rhipicephalus sanguineus (4%), Haemaphysalis concina (3%), Haemaphysalis parva (1%), Hyalomma marginatum (1%), Hyalomma anatolicum (0.6%), Dermacentor marginatus (0.6%), Ixodes ricinus (0.5%), and Boophilus (Rhipicephalus) annulatus (0.3%). Rh. turanicus was the most abundant of the studied ticks (Table 1).

Discussion

The north of Iran is in a favorable climate condition to sustain tick in the nature. The influence of weather condition on the distribution and abundance of tick species is well known. Therefore, climate change can cause diversity in tick species in a geographical area (Rahbari et al., 2007a). Global warming will affect climate condition in Iran, and new ticks species and tick-borne diseases will be spread to Iran.

Rh. turanicus (47%) was the most abundant of the total ticks in the present study. Razmi et al. (2011) reported that Rh. turanicus had the highest frequency in northern and southern parts of Khorasan Razavi province. Nabian and Rahbari (2008) identified Rh. turanicus as a rare species in Zagros mountainous area. In Africa, Rh. turanicus is present at altitudes ranging from just above sea level to over 2000 m and in regions with annual rainfalls ranging from 100 mm to 1000 mm (Walker et al., 2000). In this study, Rh. turanicus was identified in low-laying area from the sea level (like Gol Neshin in Sari) and land with 1770 m above the sea level (kou estakhr). Rh. turanicus has been identified as a vector of Babesia ovis to the susceptible hosts (Shayan et al., 2007).

Nabian et al. (2007) found Rh. Sanguineous (42.37%) as the most prevalent species in Mazandaran province. Hosseini et al. (2010) reported Rh. Sanguineous (82.4%) as the most abundant species in Ghaemshahr suburbs. Shayegehi et al. (2005) recorded that Rh. Sanguineous (1.8%) had a

Table 1. Frequency of Tick species on the studied region.
low number in Mazandaran province (1.18%) in 2002-2003.

The frequency of Rh. sanguineus (4%) was low in the present study. This finding is in contrast with the results of Nabian et al. (2007) and Hosseini et al. (2010) and is in line with the finding of Shayeghi et al. (2005). The preferred host for Rh. sanguineus is the domesticated dog (Walker et al., 2000). The agent of canine tick fever, Babesia spp. in dogs and Ehrlichia canis can be transmitted by this tick.

In contrast with the study of Nabian et al. (2007) and Shayeghi et al. (2005) who did not find Rh. bursa, this species was observed as the second numerous species (24.66%) in the present study. Hosseini et al. (2010) found this species in a very small number in Ghaemshahr. Shayeghi et al. (2005) did not find this species in a very small number (37.28%) in Mazandaran province. Hosseini (2010) recorded this species in a large number (17.16%) as the third prevalent species in Mazandaran's countryside. However, in the present study, Rh. bursa was found in land with 1770 m above the sea level (kou estakhr). R. bursa can transmit B. bigemina, B. bovis, Anaplasma marginale to cattle, B. equi, B. caballi to horses, B. motasi, B. ovis, A. ovis to sheep. CCHF virus was isolated from this tick (Walker et al., 2000).

Haem. punctata (17.16%) was found as the third prevalent species in Mazandaran's countryside. Nabian et al. (2007) recorded this species in a large number (37.28%) in Mazandaran province. Hosseini et al. (2010) found this species in a very small number in Ghaemshahr. Shayeghi et al. (2005) did not find this species in Mazandaran province in 2002-2003. This species was reported by Mazlum (1968, 1971) in the mountainous areas in the north of Iran. In this study, Haem. Punctate was just identified in the mountainous area (kou estakhr). Haem. punctata is the vector of B. motasi and B. major and carries Rickettsia siberica and causes tick paralysis (Yin et al., 1996).

Haem. concina (3%) and Haem. parva (1%) were recorded in our study to have a small number. Nabian et al. (2007), Hosseini et al. (2010) and Shayeghi et al. (2005) did not report these two species in Mazandaran province. Filipova et al. (1976) mentioned Haem.parva and Haem.concina are rare species encountered in Iran; they can be found in Caspian sea, mountainous, and semi-dessert zones of the country. Delpy (1938) found Haem. concina on sheep, cattle and horses in mountainous areas of Caspian zone. Haem.parva transmit Theileria sergenti and Crimen-Congo hemorrhagic fever virus (Shchelkanov et al., 2005). Haem. concina is observed in the east of Caspian sea zone and the southern mountainous areas (Rahbari et al. 2007b). This tick was found infected with A. bovis, Rickettsia hulini, Borrelia and Francisella tularensis (Rahbari et al., 2007b). Haemaphysalis spp. were dominant species in kou estakhr in September.

Hy. marginatum (1%), Hy.a. anatolicum (0.6%), D. marginatus (0.6%), I. ricinus (0.5%) and B. annulatus (0.3%) were observed in a very small number during inspecting infested sheep and goats. Nabian et al. (2007) did not find Hy. marginatum, D. marginatus and found Hy.a. anatolicum (3.38%) and Lricinus (3.38%) in a small number in Mazandaran. The frequency of B. annulatus was reported as 10.16% by them. Hosseini et al. (2010) observed L.ricinus (15.2%) and B.annulatus (1.2%); however, he did not find the other abovementioned species.

Shayeghi et al. (2005) reported the frequency of Hy. marginatum (1.66%), Hy.a.anatolicum (1.33%), D.marginatus (1.72%), Lricinus (27.45%), B. annulatus (8.34%).

According to the finding of Vahedi-Noori et al. (2012) activity of Lricinus in Mazandaran is dependent to the cold and humid month of the year, therefore probably this is the cause that we didn't find this tick in the summer in Mazandaran. L ricius was found in May and September in Savad Kooh. This tick is mostly found in Northern Turkey that has a high rain fall and tense forest (Aydin and Bakirci, 2007).

Walker et al. (2000) emphasized that Borrelia burgdorferi and A. phagocytophilia were transmitted by Lricinus. Morisod et al. (1972) described that B. bovis was transmitted by this tick.

In the present study, D.marginatus was identified just in the mountainous area of Mazandaran province. This finding is in accordance with Nabian et al. (2008) who emphasized this tick could hardly adapt in low-lying areas from the sea.

Black sea climate and tick fauna in Turkey are similar to those of northern Iran (Aydin and Bakirci, 2007). Amblyomma variegatum have been found in the border of Turkey to the Syria, with warm and
semidesert climate condition. This tick has not been reported from Iran until now.
