ABSTRACT

We hypothesized that plasma adipokine concentrations of early-lactation dairy cows are related to body condition score (BCS) at calving and to markers of metabolic status of the cow. As part of a larger study with 117 multiparous Holstein dairy cows, which had high BCS (BCS >4.0) or normal BCS (3.25–3.5) at calving, 22 cows were randomly selected (n = 11 per group) to be enrolled in this study. Cows were divided into 2 groups based on their BCS at calving: (1) normal BCS with BCS of 3.35 ± 0.13 (mean ± SD) and (2) high BCS cows with BCS of 4.14 ± 0.17. The 22 selected animals did not have a clinically diagnosed health problem after calving. Blood samples were taken right after calving (d 1) and before morning feeding on d 8, 15, and 21 postpartum concurrently with body condition scoring for all cows. Blood samples were analyzed for plasma adiponectin, leptin, tumor necrosis factor-α, and IL-6. The mean BCS remained highest in high-BCS cows during the first 21 d in milk. Leptin concentrations decreased progressively for all cows after calving. However, differences in BCS at calving were not related to leptin concentrations. Adiponectin, IL-6, and tumor necrosis factor-α concentrations were neither influenced by days in milk nor BCS after calving. Leptin and the leptin-to-adiponectin ratio did not show any correlation at any time point during the first 21 d in milk with plasma concentrations of nonesterified fatty acids or β-hydroxybutyrate, which are considered as markers of metabolic status. Only for IL-6 at d 8 did we find a strong correlation with metabolic status indicators. In conclusion, plasma adipokine concentrations during the first 3 wk postpartum were not related to BCS in lactating Holstein cows that were clinically healthy at calving.

Key words: dairy cow, leptin, adiponectin, tumor necrosis factor-α, interleukin-6

Short Communication

Adipose tissue is an important endocrine organ that secretes several bioactive molecules termed adipokines, which are involved in the regulation of whole body metabolism and immune responses (Fantuzzi, 2005; Trayhurn et al., 2006). Adiponectin and leptin are among the most important adipokines in the control of energy homeostasis (Havel, 2002). In humans, plasma leptin concentrations are positively correlated with degree of adiposity (Considine et al., 1996) and insulin resistance (Matsubara et al., 2000). In general, low concentrations of adiponectin are associated with an obese phenotype and with the release of inflammatory proteins (Weyer et al., 2001; Yang et al., 2001). Concentrations of these 2 adipokines in plasma have been associated with the occurrence of certain metabolic diseases, and it has been proposed that they can be used as chemical markers for diagnosis of obesity and obesity-related disorders in humans (Considine et al., 1996; Shimomura et al., 1999). Moreover, the ratio of leptin to adiponectin has been suggested as a potential index for obesity in some mammalian species, such as cynomolgus monkeys (Chen et al., 2003), and as a potential index for coexistence of obesity and type 2 diabetes mellitus in human patients (Satoh et al., 2004). Concentrations of other adipokines in plasma are also increased in the obese state. Tumor necrosis factor-α (TNF-α) and IL-6 are 2 important proinflammatory adipokines that promote insulin resistance, and they have been linked with obesity-related diseases such as diabetes type 2 (Goyal et al., 2012). In addition, it is known that adiponectin is correlated negatively with TNF-α and IL-6 (Lira et al., 2018).
Milk yield was recorded once weekly at d 8, 15, and 21 postpartum. Concurrently, milk samples from each of the 3 daily milkings were taken, pooled, and stored at −21°C until analysis for fat and protein concentrations by using a Milko-Scan 33 (Foss Electric, Hillerød, Denmark). Energy-corrected milk (4% fat, 3.3% protein) was calculated using the following equation: ECM = (milk production × 0.383 × fat % + milk production × 0.242 × protein % + 0.7832 × milk production)/3.1138. Blood samples were collected by venipuncture from the coccygeal vein right after birth (d 1) and on d 8, 15, and 21 postpartum before the morning feeding. Blood was collected into heparinized vacutainer tubes, and plasma was separated immediately after by centrifugation at 1,300 × g for 15 min at 4°C. Aliquots of plasma were stored at −80°C for later analyses. Plasma leptin was analyzed with an enzyme immunoassay that has been validated for use in several species, including bovine (Sauerwein et al., 2004). The mean intra-assay coefficient of variation was 3%, and the inter-assay coefficient of variation was 3.4%. Plasma adiponectin was analyzed by a competitive ELISA, as described by Mielenz et al. (2013). The intra- and inter-assay coefficients of variation were 5.6 and 8.2%, respectively. Concentrations of IL-6 and TNF-α in plasma were determined by commercial high sensitive ELISA kits for bovine IL-6 (kit SEA079Bo; USCN Life Science, Wuhan, China) and bovine TNF-α (kit Q06599; Thermo Fisher Scientific Inc., Waltham, MA), respectively. Nonesterified fatty acid (NEFA; Wako Chemicals, Neuss, Germany; kit 436–91995) and BHB (kit RB 1008; Labor und Technik, Berlin, Germany) concentrations were measured in plasma by using an ABX Pentra 400 instrument (Horiba Medical, Kyoto, Japan).

All data were analyzed by using SPSS 21.0 (SPSS Inc., Chicago, IL). Analysis of variance for repeated measures was used to test the effect of BCS through time for all blood parameters. In this analysis, time was considered repeated with 4 levels [1 (day of calving), 8, 15, and 21 DIM]. In the analyses of blood parameters, within-animal factors and group as the between-animal factor were included in the models to test for differences between the 2 groups of animals with respect to changes of parameters over the first 21 d postpartum. Tukey test was used for the determination of differences between BCS groups. Sphericity was checked for violation with Greenhouse–Geisser corrected degrees of freedom, if this was needed (Huck, 2000). For all analyses, homogeneity of variances was tested using the Levene’s test. Differences at each time point between HBCS and NBCS groups were compared by Student’s t-test. Pearson correlation coefficients were calculated to describe relationships between the monitored variables. Moreover, simple linear regression analyses were performed.
to test the independent relations between variables that were found to be significantly correlated. Confidence interval was set at 95%. Significance and tendency differences between treatments were determined at the $P \leq 0.05$ and $0.05 < P \leq 0.10$ levels, respectively.

The forage-to-concentrate ratio of the lactation diet was 41:59 and provided 6.86 MJ of NE\textsubscript{L} per kilogram of DM and 16.7% CP. As shown in Table 1, milk yield, ECM, and milk fat or protein concentrations did not differ between HBCS and NBCS cows over the first 21 d of lactation. Milk fat and protein yields at 8, 15, and 21 DIM for NBCS and HBCS cows are shown in Supplemental Table S1 (https://doi.org/10.3168/jds.2017-14122). The average calving BCS for HBCS and NBCS groups were 4.14 ± 0.06 and 3.35 ± 0.08, respectively (mean ± SD; $P = 0.0001$). Because of the higher BCS levels at calving, the HBCS cows continued to have higher BCS than the NBCS cows even at d 21 postpartum ($P < 0.05$). Concentrations of different variables in plasma at different time points during the first 21 d after parturition are presented in Figure 1. Despite the differences in BCS at calving and the different patterns of change in BCS after calving, concentrations of leptin in plasma were at the same level in the 2 groups of cows at calving, and leptin concentrations also decreased in the same fashion in the 2 groups of cows in early lactation (Figure 1b). No differences could be established in the pattern of changes in concentrations of TNF-α (slight decrease, Figure 1e) or IL-6 (slight increase, Figure 1f) in early lactation between the 2 groups of cows.

Concentrations of BHB in plasma increased markedly over the first 21 d of lactation, when milk production also increased ($P = 0.031$; Figure 1h). Nonesterified fatty acids and BHB concentrations were not related to differences in BCS at calving, but a positive correlation was established between IL-6 at d 8 postpartum and BHB concentrations at d 8 to 15 postpartum ($P < 0.01; R^2 = 0.38–0.54$). Some correlations were also found for adiponectin and TNF-α with NEFA and for adiponectin and IL-6 with milk yield and BCS at selected time points, but these correlations were weak in all cases ($P < 0.05; R^2 < 0.33$).

Leptin is an adipose-derived hormone, which is normally believed to be downregulated in early lactation, when net energy balance becomes negative and body fat is mobilized (Block et al., 2001). It was therefore surprising that the concentrations of leptin and adiponectin in plasma did not differ between the HBCS and NBCS cows at calving and that the changes in leptin concentrations in the HBCS cows in early lactation were not more pronounced compared with the NBCS cows. Unexpectedly, the greater rate of postpartum mobilization in the HBCS cows was not reflected in differences in concentrations of the metabolic markers NEFA and BHB in plasma, and no significant difference existed in the way concentrations of the 2 markers in plasma changed in early lactation. Other studies have established positive correlations between leptin and BCS in lactating (Chilliard et al., 2005) and nonlactating, nonpregnant cows (Locher et al., 2015), and a correlation to NEB in lactating cows depending on the stage of lactation (Chilliard et al., 2005). However, Holtenius et al. (2003) found that, similar to us, leptin concentrations were unrelated to BCS after calving in lactating, nonpregnant dairy cows.

Some studies have indicated that BCS in dairy cows during the dry period may be more closely associated with adiponectin than with leptin (Locher et al., 2015), but this negative correlation may disappear as parturition approaches, because adiponectin concentra-

\(^1\)NBCS = normal BCS (3.25–3.50), n = 11; HBCS = high BCS (≥4.0), n = 11.
tions gradually approach a nadir at this time point (De Koster et al., 2017). During early lactation, loss of adiposity associated with NEB may thus become more important in determining adiponectin concentrations, rather than the degree of body fatness per se (Giesy et al., 2012; Singh et al., 2014; De Koster et al., 2017). It may explain why the extent of body fatness in our experiment was not associated with either leptin concentration or leptin-to-adiponectin ratio at calving, and the correlations found between adiponectin and BCS were weak. Thus, in contrast to results of human studies (Oda et al., 2008), we and others (Singh et al., 2014) have been unable to find any evidence to suggest that leptin and leptin-to-adiponectin ratio could be useful markers for metabolic disorders in the bovine animal.

Tumor necrosis factor-α was the first adipokine for which it was shown that its concentrations in blood increase in obese humans, and concentrations decrease...
after weight loss (Dandona et al., 1998). Tumor necrosis factor-α has a stimulatory effect on leptin formation (Zumbach et al., 1997) and inhibits adiponectin secretion in rodents (Ruan et al., 2002). However, in our study, because of the different patterns of changes of these hormones in the early postpartum period, no such correlations could obviously be established. Observations regarding the association between BCS and concentrations of TNF-α in plasma of dairy cows are conflicting. In a study by O’Boyle et al. (2006), high-BCS, mid-lactating dairy cows (>3.5) were found to have higher TNF-α concentrations compared with their normal counterparts (BCS 2.5—2.7), as in the human study (Dandona et al., 1998). However, Ohtsuka et al. (2005) failed to establish any relation between BCS and TNF-α concentrations in plasma of dairy cows suffering from fatty liver, and in a study by Røntved et al. (2005), TNF-α concentrations in plasma were unaffected by changes in energy status of dairy cows in early lactation. These latter observations are in line with our study, where we were unable to demonstrate any significant differences in TNF-α concentrations in plasma between HBCS and NBCS cows at any time point during early lactation. If anything, HBCS cows had the numerically lowest concentrations, particularly at calving, compared with the NBCS cows (Figure 1e), opposite of what was observed in humans (Dandona et al., 1998). Unlike adiponectin and leptin, which are secreted almost exclusively by adipocytes, TNF-α is secreted mainly from macrophages and less from adipocytes (Maury et al., 2009). Thus, it is reasonable to assume that the inflammatory state of the cow has a much more dominant role in determining concentrations of TNF-α in plasma compared with NEB. Nonesterified fatty acids and BHB concentrations in plasma in this study never reached levels that indicate a degree of ketonemia, which would have been expected to elicit a response in this inflammatory marker (Abuaajamieh et al., 2016), and changes in concentrations of NEFA and BHB were not related to those of TNF-α. We speculate that physiological factors, such as the time interval to parturition, may have a greater influence on TNF-α concentrations in plasma than adiposity per se in the apparently healthy periparturient dairy cow, and this assumption is supported by observations that plasma TNF-α increases as parturition approaches and decreases thereafter (Ametaj et al., 2005), as we also observed.

Our results showed that the only adipokine related to the 2 metabolic markers NEFA and BHB in clinically healthy cows was IL-6. Plasma IL-6 at d 8 postpartum was positively correlated with NEFA at d 21 (r = 0.54, P = 0.025) and with BHB at d 8, 15, and 21 (r = 0.67, r = 0.62, and r = 0.72, respectively; P < 0.01). These results are in agreement with other studies, where IL-6 concentration has been linked to metabolic changes observed in ketotic cows (Loor et al., 2007; Zhang et al., 2016) and to the severity of inflammatory responses in early-lactating dairy cows (Trevisi et al., 2012). Dairy cows in this study were under a high management level, and the periparturient diets contained propylene glycol, a gluconeogenic substrate that is given to promote glucose supply for milk synthesis and to prevent excessive fat mobilization and ketosis (Christensen et al., 1997). Therefore, this may explain, in part, why the postpartum increases in NEFA level in HBCS were relatively modest to low in most of the time points in early lactation (<550 µmol/L). The picture could be different in cows with more extensive fat mobilization, resulting in higher NEFA concentrations. Thus, our study suggests that BCS is not a major determining factor of adipokine levels after calving; rather, such changes may be related to an adipose-tissue dysfunction following extensive fat mobilization.

Finally, the anatomical location of body fat mobilization may affect the concentrations of adipokines in plasma, and the limitations of the BCS method used in this study obviously relate to the fact that it primarily reflects changes in fat mass of subcutaneous and peripheral adipose tissues. It has been shown in humans that plasma adiponectin, IL-6, and TNF-α are more strongly influenced by the amount of visceral fat (Park et al., 2005; Fontana et al., 2007) than by subcutaneous fat, and other factors influenced by NEB could potentially influence the set point for their release from adipose tissues (Chilliard et al., 2005; De Koster et al., 2017).

In conclusion, body condition at calving did not have any major effect on concentrations of leptin, adiponectin, IL-6, or TNF-α in plasma of clinically healthy early-lactating dairy cows. Interleukin-6 was the only adipokine for which we could find indications of an up-regulation when concentrations of the metabolic markers NEFA and BHB in plasma for NEB were increased, but the association between changes in IL-6 and degree of fatness of the cow was not significant. Further studies are needed to resolve the underlying reasons for, and implications of, the association of IL-6 with metabolic status in early-lactating dairy cows.
